I'm doing this by transforming the document into XQuery and then using a template function to find the element. If I find the element, I update a counter in the XQuery. I then use that counter to give the element a score. The problem is that the elements being searched can get longer and longer, and the longer they are, the less reliable the match will be. For example, the below element could be anywhere in the document: The problem is that the in the XML above, the search will hit the blah.xml file and stop. The only solution I can think of is to manually create an XQuery that runs a REGEXP and matches the beginning of the longer element, and then see if the next character matches the REGEXP, etc. This feels like a really big hack, though. Is there a better way to do this? Can I instruct Saxon to be more 'greedy' in the matching? Can Saxon just break the file up into chunks that it finds? I have the feeling that this is something I'm just not seeing because I'm not used to working with XQuery on a document that is so variable and amal. A: You could try something like this: xquery version "3.0"; (:= \$x := 0) declare function fn:scan(\$xml as element(\*), \$pattern as xs:string\*) { (:= \$x := 1 + string- a1d647c40b
