The main database environments are: – Oracle – Microsoft SQL – MySQL – PostgreSQL These databases can be accessed from different application. SQL is often an integral part of an application. For example, SQL is often used to query a database from a client, a database from a web application, or from a server or to create, update or delete records. SQL has an infrastructure which can be a series of various operating system services such as: – Storage service – Network Service – SQL Process (usually a service) User, Administrator, and Database security are the main concerns in SQL database security. Each user, administrator and database has a defined role in the system. User rights are granted and revoked by the SQL users and this are the user that will be accessing a database. If a user has the correct privileges and rights to access a database, it will be granted the necessary access. The same concept applies to a database administrator, these are users that have the necessary access to the database. SQL database is a tool that is used to manage and store data and any data input is stored in a SQL database. SQL is also used to query the data stored in the database, also update and delete data. The database itself can be accessed by the user and in many cases the database can be deployed on the server side. SQL Servers: SQL Server can be used to connect to a database from different applications and can be accessed by the server and client side. There are two types of servers: – Application Server – Client Server There are two types of databases: – Local Database – Network Database Local Database: Local databases are common on the desktop and mobile devices. Local database can be accessed by any application and on the server side, it can be deployed on

SQL Server is used by a wide variety of database applications ranging from simple business applications to advanced analytic and data warehousing applications. What is Microsoft SQL Server? Microsoft SQL Server is a high-performance, open-source, fully relational database management system available from Microsoft. It is designed to help organizations build their own, private-label databases to address their individual needs. SQL Server is also used by a variety of database applications ranging from simple business applications to advanced analytic and data warehousing applications. What is a relational database management system? A relational database management system (RDBMS) is an application that manages relationships between data and serves as a computerized information repository. Using this relationship, data is stored in tables or relations (plural) and retrieved by executing queries or statements against the database. It is a database management system in the sense that it organizes, manages, and stores data. What is a relational database? Relational databases store data in tables and relate data through primary and foreign keys. A relational database structure can be comprised of several different tables. Tables are the most basic building blocks of a database. Tables represent relations between the data stored in them. What are primary and foreign keys? In a relational database, data is stored in a table. A primary key is a value used to identify a row or record. Primary keys are used to relate the rows of a table to one another and are called identifying keys. In relational databases, each table has a primary key. A foreign key is another key used to relate a row in one table to the row in another table. A foreign key is not required but is frequently used. For example, a link between an order and an order line would have both a primary and a foreign key. What is a relational database? A relational database is a database management system in which data is stored in tables and related via primary and foreign keys. It is a tool used for storing and retrieving data from a computer.
