The design is a bit more challenging than in the case of the LM1496. As with the LM1496, this IC consists of differential amplifiers with the following gain stages. Description. Overview. Recently active sections. Hardware Description. This circuit is an improvement of the LM1496 circuit described here by Howard Johnson. Description. Technical Information. Select Hardware. Clear All. . Description. You can download the sources, edit them and make your own changes by using SnapEDA's open source design IDE or you can simply download the sources. In this case, the left differential amplifier is the LM1496 itself and the right differential amplifier is the AD630. Next you will need to figure out how many resistors are needed in the middle of the bridge. When doing this, you will need to consider the V<sub>dd</sub> that the circuit is going to be running off of, as well as the supply voltage that the circuit is going to be used with. As with the LM1496 circuit, this one outputs into two supply rails and two ground rails. The rail to rail voltage is 10V. The LM1496 is a simple balanced modulator /demodulator. For example, if your project is to interface a sensor that looks like this: The output of the sensor comes out on these pins: . It's basically a 1 volt analog output signal that's connected to ground. And the ground pins output 1 volt analog signal that is connected to 5 volts. The difference voltage is output out of pin 1. Pin 2. The output is then wired to pins 5 & 8 of a standard 5 volt switching MOSFET. The switches are configured to put the output voltage on the ground pins and then to the 5 volt pins. The same idea can be applied to this circuit. Can you figure it out by looking at the schematic above? The MC1496 uses a common mode feedback (CMFB) technique to provide very high Q balanced modulator/demodulator circuits. A 180 mV modulation of a signal at baseband (0-100 Hz) will result in a modulation at the modulator output of less than 40 pV (20 Hz) and a modulation at the demodulator output of less than 20 fV (40 Hz). The output devices are high impedance, and the insertion loss is very small. Here is a basic configuration of the circuit. It is designed to amplify a
