Q: Windows Service vs Workstation process

The most common scenario is a program running on a client machine that connects to the

database using a sql connection object to perform inserts and updates. Is there any difference in the functionality between a service vs a workstation process (both of them under local system account)?

The difference I can see is the possible unavailability of the process (but I believe this can be handled with the sql connection object). Any thoughts? A: Under normal operation (say, when not responding to a user command), a service is a separate thread. The thread is not blocked by the user interface. If you want to stop it, you just kill the service. Services have been made in anticipation of that sort of thing, they can gracefully shut down, release any file handles they have, and so forth. The subproject and investigator (PI) may have received primary funding from another NIH source, and thus could be represented in other

We are interested in determining the molecular details of how vertebrate retina outer segments are assembled. Outer segments are crucial to the visual transduction process in vertebrate photoreceptors, and are the site of production of the visual pigment molecules and of the rhodopsin receptors. They are assembled in the cell body, and then secreted to the apical surface of the rod and cone outer segments. They grow by addition of membrane from the inner segments and by phagocytosis of debris. They are replaced continuously. During a1d647c40b
